KINEMATICS

SUMMARY

- ▶ Largest survey of spatially resolved **gas kinematics**, **morphologies** and **physical properties** of **star forming galaxies** at  $z \sim 1 - 3$
- ▶ **SINS H $\alpha$  sample**: 62 objects were detected in rest-frame UV: **H $\alpha$**  (656.28nm) & **NII** (double line emission: 654.8nm and 658.3nm).
- ▶ Reasonable representation of Massive  $M_{\star} \geq 10^{10} M_{\odot}$  galaxies.
- ▶ Population analysis:
  - ▶ 1/3 Rotation dominated turbulent disks
  - ▶ 1/3 Compact and Velocity dispersion dominated objects
  - ▶ 1/3 Interacting/Merging systems
- ▶ Massive galaxies tend to be more "rotation dominated".
- ▶ H $\alpha$  Luminosities and equivalent widths:
  - ▶ Twice higher dust attenuation towards the HII regions.
  - ▶ Comparable current and past-averaged star formation rates.

KINEMATICS

SUMMARY

- ▶ The **global population properties** of the galaxy are generally understood:
  - ▶ Rapid evolution in  $z \sim 1 - 4$
  - ▶ Downsizing
  - ▶ Color bimodality and Hubble sequence originate from  $z \sim 1 - 2$ .
- ▶ Current (before this paper) dependencies:
  - ▶ SED fitting and color analysis
  - ▶ Global properties such as: Stellar mass, age, SFR, interstellar extinction and sizes.
  - ▶ Limited integrated spectroscopy in the NIR. **More direct and detailed constraints needed**
- ▶ **Important question:** How massive galaxies assemble their mass?
  - ▶ Major mergers
  - ▶ Cold flows and Minor mergers

SUMMARY

FIGURE: Förster Schreiber et al. 2006.

- ▶ Diversity in Kinematics and Morphologies of  $H\alpha$  sources.
- ▶ Large fraction having disk like rotation.

# GENERAL PROPERTIES

- ▶ Full sample: 80 spectroscopically confirmed galaxies with 63 observed in one emission line.
- ▶ Selection criteria:
  - ▶ Target visibility
  - ▶ Night sky line avoidance for  $H\alpha$  or  $[OIII]:5007\text{\AA}$
  - ▶ Emission line flux of  $\geq 5 \times 10^{-17} \text{ ergs}^{-1} \text{ cm}^{-2}$ . (Estimated with SED fitting for 2/3 of the final samples)
- ▶ AGNs were avoided, but present: line emission could be spatially or spectrally separated.

KINEMATICS

SUMMARY

- ▶ **Optical: BM/BX:** Actively star-forming with moderate extinction in  $z \sim 1.5 - 2.0$ (BM) and  $z \sim 2.0 - 2.5$ (BX). Selected by spectroscopy with the NIRSPEC at Keck II.
- ▶ **Near Infra-Red**  
**sBzK:** More specifically evolved and/or dust-obscured populations of star-forming (sBzK) that may be under-represented in optical surveys.
  - ▶ **K20 survey** (5): Previously observed  $H\alpha$  and [NII].
  - ▶ **Deep-3a survey** (7): bright at  $24\mu m$  with flux  $\geq 100\mu J$ , AO.
  - ▶ **GMASS survey** (19):  $4.5\mu m$  selected.  $H\alpha$  flux estimated and non-elliptical morphologies.
  - ▶ **zCOSMOS-deep survey** (4): sBzK with  $1.4 < z_{sp} < 2.5$ ; morphology was also a criterion
  - ▶ **GDDS survey** (8): redshift range and on going star formation.
- ▶ **Lyman Break Galaxies:** Mainly taken from Steidel et al. 1999.
- ▶ **Submillimeter Bright Galaxies:** Accurate positional and spectroscopic information.
- ▶ **Line emitters:** In the vicinity of radio source MRC1138-262 and NIC J1143-8036a/b.

SUMMARY

## Bias

- ▶ The variety lowers bias compared to separate samples
- ▶ Optical  $z_{spec}$ : **UV-brighter galaxies**
- ▶ Minimum  $H\alpha$  flux: **younger galaxies**

## Reference Population:

- ▶ Chandra Deep Field South (CDFs) catalog used for comparison
- ▶ Sources with  $K_{s,vega} < 22$  and  $z_{photo}$  in the same range

Characteristics (e.g. Mass, Age and etc.) could not be used from the catalogs because each used different assumptions in modeling.

- ▶ **All galaxies were remodelled**: newer results (compared to the base catalogs) were used in this process.
- ▶ **Total photometric** uncertainties were either given or found from the original images. **Galactic extinction** towards various fields were also considered.
- ▶ Bruzual & Charlot (2003) synthesis code was used:
  - ▶ Fixed solar metallicity, Chabrier (2003) IMF, Calzetti (2000) reddenning and Madau (1995) intergalactic H opacity,  $\lambda_{rest} \leq 912\text{\AA}$  was set to zero.
  - ▶ Star Formation History + Dust models considered:
    - ▶ Constant Star Formation + dust
    - ▶ Instantaneous Star Formation + No dust
    - ▶ Exponentially declining SFR ( $\tau = 300\text{Myr}$ ) + dust
- ▶ Synthetic spectra were convolved with a filter curve
- ▶  $H\alpha$  redshift (optical when not applicable) taken as base redshift

COMPARISON

DUST DISTRIBUTION  
& STAR FORMATION

KINEMATICS

SUMMARY

- ▶ **Age, Extinction & luminosity scaling** were taken as free parameters in the fitting and found through  $\chi^2$  minimization
- ▶ Acceptable age:  $50\text{Myrs} < \text{Age} < \text{Age\_of\_universe}$ .
- ▶ Best of three SFHs, was taken as true SFH.
- ▶ Errors in free parameters from 200 Monte-carlo simulations on observed SEDs.
- ▶ Emission line contribution was **not corrected** for:
  - ▶ All emission lines could not be accounted for in all galaxies.
  - ▶  $H\alpha$  was on average only 10% of all emission lines.
  - ▶ Since trends are necessary here, the effect is very low.
- ▶ **Errors (Monte Carlo simulations) not considered:** Metallicity, Reddening, IMF, Synthesis code & SFH.
  - ▶ Poorly understood for  $z \sim 2$  universe
  - ▶ Not too significant in trends
  - ▶ Same effect on the CDFS galaxies

SUMMARY

## SINFONI:

- ▶ Adaptive Optics (MACAO)
- ▶ Integral Field Spectrometer (SPIFFI)

The final image of SINFONI is a 2D spatial array of  $64 \times 32$  pixels and the spectral dimension is: 2048 pixels

SUMMARY

# DATA COLLECTION

- ▶ 24 observing campaigns: 03/2003 to 07/2008.
- ▶ Based on redshift **H** or **K** gratings were used for  $H\alpha$
- ▶ 8 objects observed with AO
- ▶ Sky subtraction:
  - ▶ Onsource dithering (majority)
  - ▶ Offsets-to-sky
- ▶ Individual exposures: 300s, 600s & 900s
- ▶ Total integration times: 20min to 10h
- ▶ Observation did not continue if  $H\alpha$  emission was not visible after 1-2hrs.
- ▶ **Data reduction procedures are omitted here**

KINEMATICS

SUMMARY

- ▶ The PSF for each object was obtained from nearby stars
- ▶ All adequate were averaged to **achieve higher  $S/N$** , normalized to unity and  $5\sigma$  clipped.

- ▶ Narrow core and broad component: **elliptical Gaussian**
- ▶ Model galaxies (in spectroscopy and photometry) were constructed and convolved with various PSFs to find that **uncertainties in PSF size have a small impact on the kinematic properties derived.**

KINEMATICS

SUMMARY

- ▶  $\sigma_{real} \neq C \times N \times \sigma_{pix}$ :

- ▶ slitlet projection.
- ▶ special data reduction method.

- ▶  $\sigma_{real}$  was calculated by the dispersion in the dispersion of apertures of  $N$  pixels taken from empty regions of each wavelength's 2D image.

- ▶  $\sigma_{real}$  shows this behavior:

$$\sigma_{real}(N, \lambda) / [N \times \sigma_{pix}(\lambda)] = a(\lambda) + b(\lambda) \log N$$

- ▶ It is found that  $a$  and  $b$  are independent of  $\lambda$ , so the median value of each was taken.
- ▶ Finally, to find the noise for each measurement this relation was used:

$$\sigma_{real}(N, \lambda) = [N \times \sigma_{pix}(\lambda)] \times (a_{med} + b_{med} \log N)$$

- ▶ The noise from this method is on average  $\times 2$  the Gaussian noise assumption.

SUMMARY

Velocity integrated line fluxes, Relative velocities and Velocity dispersion were calculated using LINEFIT.

- ▶ Data cubes median filtered (2 or 3 pixel wide filter)
- ▶ Instrumental resolution through sky lines
- ▶ *Uniform, Gaussian or Poisson* weighted fits are preformed.
- ▶ Continuum component subtracted
- ▶ Fitting uncertainties are computed from 100 monte carlo simulations.
- ▶ Asymmetries observed: *Double peak profiles, Faint-blue/redshifted tails and multiple components.*

Spectral points were obtained from 90% circular apertures of the  $H\alpha$  image of each cube.

Integrated velocity dispersion ( $\sigma_{int}(H\alpha)$ ) was calculated without shifting of the spectra

KINEMATICS

SUMMARY

- ▶ Morphological major axis was **usually** within  $20^\circ$  of the kinematic major axis: direction of maximum  $H\alpha$  gradient.
- ▶ The **kinematic P.A.** was taken as the major axis.
- ▶ Gaussian profile is assumed for the  $H\alpha$  sources
- ▶  $r_{1/2}(H\alpha)$  from  $H\alpha$  curve-of-growth analysis and corrected for seeing
- ▶ PSF variations are of order 20%; size uncertainties in the order of  $\approx 30\% - 35\%$
- ▶ Typical detection limit, not straightforward:
  - ▶ Sensitivity varies with wavelength.
  - ▶ Wide range of integration times.

KINEMATICS

SUMMARY

- ▶ Similar trends seen in all three cases
- ▶ Those identified as Disks and Mergers tend to higher horizontal values.
- ▶ AGNs are **red outliers**.
- ▶ Sensitivity limits:
  - ▶ Dashed line: Sensitivity limit
  - ▶ Bold line: Exposure time limit (1h); **Observation strategy**.

# COMPARISON WITH ERB ET AL. 2006 $z \sim 2$ SAMPLES

## With NIRSPEC Long-slit spectroscopy

- Higher fluxes with SINFONI by  $\times 1.6$ ;  
Slit loss & Slit miss-alignment.
- Over all, Slit Spectroscopy seems to be highly reliable.

KINEMATICS

SUMMARY

Is  $H\alpha$  from Star forming regions or AGNs or shock-ionized material?

## From Star forming regions:

- ▶ Rest-frame optical line ratios (e.g.  $[NII]/H\alpha$ )
- ▶ Rest-frame UV spectra
- ▶ In one of four AGNs,  $H\alpha$  is dominated by star-forming regions.

## From AGNs:

- ▶ Shapiro et al. 2009 show a broad underlying  $H\alpha$  component in all SINS samples  
Could be due to lower level or obscured AGN
- ▶ AGNs would also affect the SED results

DUST DISTRIBUTION  
& STAR FORMATION

KINEMATICS

SUMMARY

## $H\alpha$ Luminosity:

- ▶ SED fitting extinction:  $A_{V,SED}: L^0(H\alpha)$
- ▶ Extinction due to dust:  $A_{V,Neb} = A_{V,SED}/0.44: L^{00}(H\alpha)$
- ▶ Calzetti et al. 2000 redenning:  $A_{H\alpha} = 0.82 \times A_V$
- ▶ Balmer absorption and Galactic extinction neglected.

## $H\alpha$ Equivalent width:

- ▶ Ratio of  $H\alpha$  line flux to Broad band flux densities:  $W_{BB}^{rest}(H\alpha)$
- ▶ Measurements of line-free continuum of the integrated spectra:  $W_{SINF}^{rest}(H\alpha)$

SFR found by Kennicutt(1998) paper:

$$\log(SFR(H\alpha)[M_{\odot}/yr]) = \log(L(H\alpha)[erg/s]) - 41.33$$

SUMMARY

## Disk or Merger:

- ▶ *Quantitative*: Degree of asymmetry; 10 Disks, 5 Mergers
- ▶ *Qualitative*: Similar fraction of disks and mergers

## Rotation/Dispersion Dominated:

- ▶ *Reliable*:  $v_{rot}/\sigma_0 = 1$ ; 13 rotation & 1 dispersion dominated.
- ▶ *Simulations*: The above boundary can be translated to:  
 $v_{obs}/(2\sigma_{int}) \sim 0.4$ :  $\sim 1/3$  of sources are dispersion dominated.

So:  
1/3 Disks,  
1/3 Mergers,  
1/3 velocity dispersion dominated (mainly compact and low mass)

- ▶  $v_{rot}/\sigma_0 \sim 1 - 7$ ; for local galaxies: 10 – 20
- ▶ So the variations in rotational velocity are very high; Thick disks and high turbulence.  
Has been confirmed directly and indirectly by other studies
- ▶ Possible origins for this turbulence:
  - ▶ Intense star formation **Feedback**.
  - ▶ Heating due to **Gas accretion**.
  - ▶ Stirring due to **Internal dynamical processes**.
- ▶ On AO observed sources, deviations from pure rotation on kpc scale have been noticed.

- ▶ Tend to be more compact
- ▶ Very low values of velocity gradients are observed
- ▶ What can they be?
  - ▶ Small disks with **unresolved rotation**.
  - ▶ Nearly **Face on disks**.
  - ▶ Systems with **random/non-circular kinematics**; e.g. late stage mergers or very young systems.
- ▶ Law et al. (2009), studying less massive galaxies found a larger fraction of such sources.

KINEMATICS

SUMMARY

- ▶ Consisting of rotation or dispersion dominated components.
- ▶ Cannot be classified by integrated  $H\alpha$  or stellar properties.
- ▶ Selection Criterion:
  - ▶ Projected separations  $\leq 15 - 20kpc$ .
  - ▶ Elevated Star Formation.
  - ▶ Perturbed and asymmetric gas kinematics on 1-5kpc scales.
- ▶ Such phases occur on a very short time scale ( $\sim 100Myr$ ).
- ▶ Morphological analysis of mergers is necessary for a complete analysis.

SUMMARY

The Law et al. 2009 sample was also included.

$v_d$  is the circular velocity:

- ▶ **Kinematic modelling**

- ▶ **Velocity Gradient + width:**

Rotation dominated,  
average of:

$$v_d^{vgrad} \sin(i) = 1.3 v_{obs}(H\alpha)$$

and

$$v_d^{width} \sin(i) = 0.99 \sigma_{int}(H\alpha)$$

- ▶ **Velocity Width:** dispersion dominated, virial relation:

$$v_d = \sqrt{3} \sigma_{int}(H\alpha)$$

COMPARISON

DUST DISTRIBUTION  
& STAR FORMATION

KINEMATICS

SUMMARY

- ▶ Reasonable sample of **Massive**, actively **star-forming** galaxies at  $z \sim 2$
- ▶ **Differential Extinction** between HII regions and stars is seen.
- ▶ SINS galaxies have undergone a roughly **Constant SFR**.
- ▶ They have **Large velocity dispersion**:  $\sim 30 - 90 \text{ km/s}$
- ▶ Gas kinematics is often surprisingly **ordered**.
- ▶ *Rotation dominated, Velocity dispersion dominated and Mergers/Interactions* are **equally distributed**.
- ▶ The rotation dominated galaxies follow a **velocity-size relation** and tend to be more **massive**.
- ▶ The dispersion dominated galaxies have **lower mass** and **lower angular momentum**; have a wide range of ages.
